Is not a commitment, promise or legal obligation to deliver any material, code or functionality.

The development, release and timing of any features or functionality described for IBM products remain at IBM's sole discretion.

The Properties View Designer

Objectives

This lesson is designed to introduce you to the Properties View Designer feature.

- How property views are used
- Default, system-generated, or custom views
- Using the view editor

Properties Views

- The property view designer was introduced in ICM 5.2.
- It allows customized views of properties to be displayed in case pages
- Custom property views may in some cases replace the need for:
 - Forms
 - Custom Widgets

Properties Views

- A properties view is loaded and used by a properties widget, based on the case type, to know what properties to display and how to display them.
- Each case type has a “default view”. This is the properties view that will be used for this case type if a particular page's properties widget is not configured to use a particular custom view.
- There is a “system generated” view that is available automatically, and is automatically set as the initial default view, when designing a case type.

More about Properties Views

- Properties Views and Forms use a shared “controller” in a Model/View/Controller paradigm
 - The Model is the Model API
 - The View is what you create with the view editor
- Therefore, changing a property in a particular properties view may change the same property elsewhere:
 - Multiple properties views on the same page
 - Forms widgets on the page
 - Same property used in multiple places within a single properties view

Automation of view fields

- There is a Model API for the property controller layer, allowing accessing fields.
- It could be used by a script (Script Adaptor or custom widget), possibly also using External Data Services, to pre-populate fields.
- If you want a value to be displayed but not be a case property, use a Workflow field and populate it using a process that perhaps uses EDS to compute the value.

Automation of view fields (con't)

In addition, you can define a field to have a dependency on an External Data Service:

- Any change in the value of the field will be sent to the EDS
- That web service can return a change step that could update that field and/or other fields.
- The updates can also change metadata of fields, such as setting a field to be read-only/not, required/not, hidden/shown, etc.
- For example, the user chooses a state, and that populates a list of cities in that state in another combo box.

Creating a new Properties View

- You give a name to each custom properties view
- To create a new properties view, within Case Builder, open the case type, click on Views on the left, then the Properties View tab. Click Add View. Give the new view a name and description and click OK to save it.

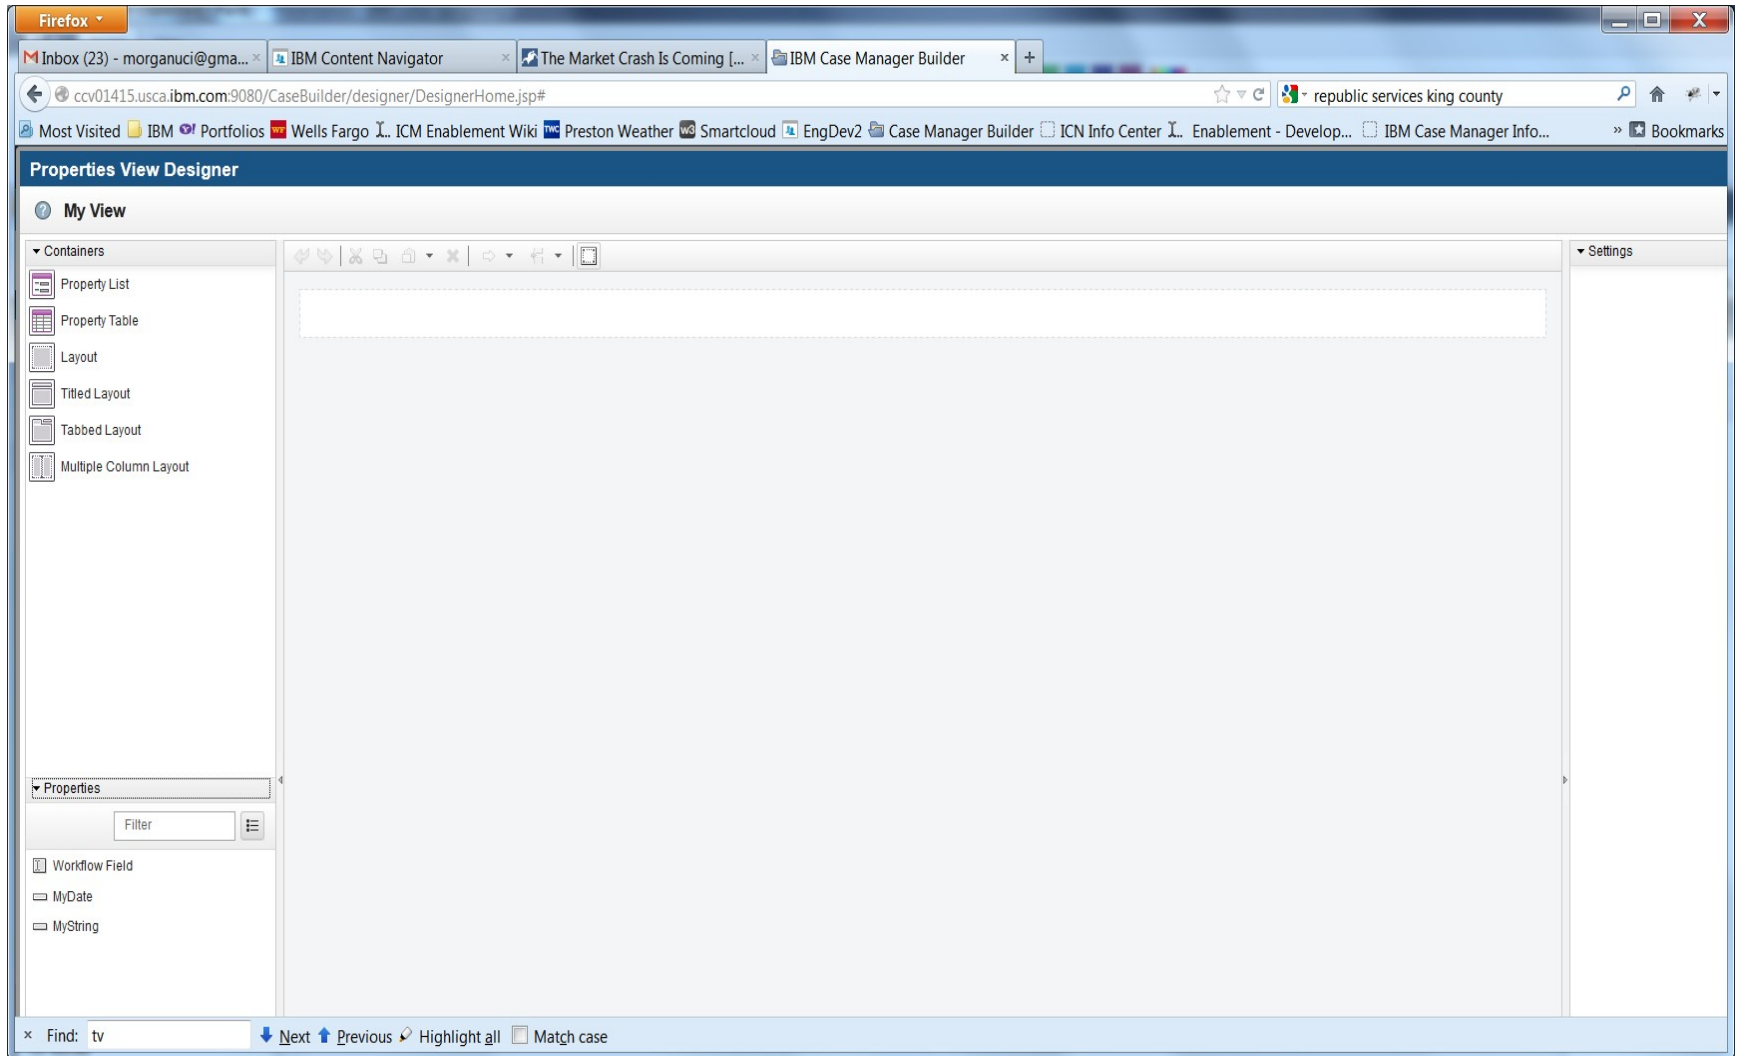

The screenshot shows the 'Case Builder' interface. At the top, there's a header bar with a question mark icon and the text 'Case Title Property: Case ID' with an edit icon. Below this is a tabbed interface with three tabs: 'Case Summary', 'Properties Layout' (which is selected), and 'Case Search'. Under the 'Properties Layout' tab, there's a sub-header with 'Add View' and 'OK All' buttons, and a 'Default view:' dropdown menu set to 'Job Application'. Below this is a table with two columns: 'View Name ^' and 'Description ^'. The table has two rows. The first row has 'Job Application' in the 'View Name' column and 'Job Application View' in the 'Description' column. The second row is empty. To the right of the table are 'OK' and 'Cancel' buttons.

View Name ^	Description ^
Job Application	Job Application View

Creating a new Properties View

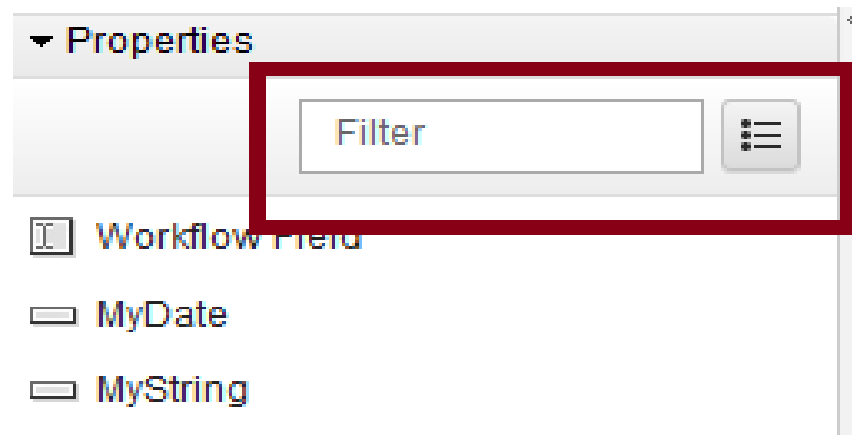

- Once you've created a new view, click on its name to open it in the editor.
- This opens a new screen with three regions:
 - Palettes (Containers and case properties) are listed on the left
 - A canvas area in the middle
 - Settings on the right
- These regions can be “undocked” and float
- One of the listed properties is “Workflow field”. It allows you to place a WF field just like other properties, rather than always listed at the bottom.
- See screen shot on next slide

Properties View Editor

More about Properties View Editor

- The list of properties may be very long. Therefore, there is a filter field. Typing text there limits the list to only properties whose names contain that text.
- Notice also the button to the right of the filter field. Pressing this button removes from the list any properties that have been used in the view so far.
- If that button is not selected, then properties that have been used are displayed in a lighter gray color.

Creating a new Properties View

- The Containers are used to group properties, such as:
 - Lists
 - Tabbed views
 - Multicolumn layout
- Containers may contain other containers.
- The Property Table container is used for Multivalued Properties---the values are displayed vertically.
- Click on a container or property and drag it into the canvas.
- Control-click allows multiple properties to be selected. The order of selection determines their order on the canvas.

Property settings

- The Settings area displays attributes of whatever item is currently selected in the canvas (a container or a property).

The screenshot displays the 'Properties View Designer' interface. On the left, a 'Containers' pane lists various UI components: Property List, Property Table, Layout, Titled Layout, Tabbed Layout, and Multiple Column Layout. The central canvas shows a 'My titled layout' containing two tabs, 'My tab 1' and 'My tab 2'. Under 'My tab 1', there is a 'Date' control with two input fields showing '9/5/2013' and '12:00 PM'. On the right, the 'Settings' pane is active, showing 'Property Settings' for the selected 'Date' control. The settings include 'Label' (Date), 'Read-only' (unchecked), 'Required' (unchecked), and 'Control' (Default). Below these are 'Model Settings' for a 'datetime' type, including ID, Name, Type, Cardinality, Required, Read-only, and Hidden properties. A dropdown menu is open for the 'Control' property, showing options: 'Default', 'Date time text box', 'Date text box' (highlighted), and 'Static text'.

Property Settings	
Label:	Date
Read-only:	<input type="checkbox"/>
Required:	<input type="checkbox"/>
Control:	Default

Model Settings	
ID:	TS1
Name:	MyD
Type:	datetime
Cardinality:	single
Required:	false
Read-only:	false
Hidden:	false

Property settings (con't)

- The dotted lines on the screen indicate nested containers.
- This allows you to select a particular one to modify its settings, delete it, etc.
- There is a button at the top of the screen that toggles to show how the view will look at runtime (see next slide). Remember to turn this mode off after viewing the runtime appearance, as otherwise you can't edit the containers.
- Notice also that once the Date control is selected, the appearance changes and additional settings are displayed.

Property settings (con't)

The screenshot displays the IBM Properties View Designer interface. The top bar is labeled "Properties View Designer". Below it, the "My View" tab is active. The left sidebar contains a "Containers" list with options: Property List, Property Table, Layout, Titled Layout, Tabbed Layout, and Multiple Column Layout. Below this is a "Properties" section with a "Filter" input and a list of properties: Workflow Field, MyDate, and MyString. The main workspace shows a "My titled layout" containing two tabs, "My tab 1" and "My tab 2". Under "My tab 1", there is a date field with the value "9/5/2013". An orange box highlights a small icon in the top toolbar of the workspace. The right sidebar shows the "Settings" panel, which is divided into three sections: "Property Settings", "Control Settings", and "Model Settings".

Property Settings	
Label:	Date
Read-only:	<input type="checkbox"/>
Required:	<input type="checkbox"/>
Control:	Date text box ▾

Control Settings	
Field width:	<input type="text"/> pixels ▾
Format:	Default ▾
Date pattern:	<input type="text"/>
Minimum value:	<input type="text"/>
Maximum value:	<input type="text"/>

Model Settings	
ID:	TS1_MyDate
Name:	MyDate
Type:	datetime
Cardinality:	single
Required:	false
Read-only:	false
Hidden:	false

Property settings (con't)

- “Hints” are like tooltips---they can suggest appropriate input values for fields.
- While the Date control generates its own, others allow you to input the hint string, and whether it's placed inside the field or below it.

The screenshot shows a software development tool interface. On the left, a canvas displays a layout titled "My titled layout" containing two tabs, "My tab 1" and "My tab 2". Under "My tab 2", there is a text box control with the label "MyString:" and the hint text "Applicant's name". On the right, a "Settings" panel is open, showing "Property Settings" and "Control Settings".

Property Settings	
Label:	<input type="text"/>
Read-only:	<input type="checkbox"/>
Required:	<input type="checkbox"/>
Control:	Text box ▼

Control Settings	
Field width:	<input type="text"/> pixels ▼
Hint:	<input type="text" value="Applicant's name"/>
Hint position:	Inside ▼ Inside Outside
Pattern:	<input type="text"/>

Extending the properties view

- Extension points
 - Registry configuration – configures the available editors and the suitable mapping between data types and editors
 - Registry configuration is managed by RegistryManager. The module provides public APIs to merge customized registry configuration, enabling registering custom editors
 - Integration configuration – configures the controllers mapping and their attributes and methods
 - Integration configuration is managed by Integration.js. The module provides public APIs to merge customized integration configuration, enabling the use of custom controllers, custom data types, and customizing the attributes and methods of the controllers
- Approaches
 - Script Adapter widget
 - Extensions package

External Properties

- External properties are
 - Properties that define a collection of properties that is in its own collection and not associated with case properties or task properties
 - Meant to be defined and saved through an external source like a servlet, JSON file, or data service
 - Added to the Properties widget using script adapters
- External property binding is handled by the Properties area in the Model layer

External Properties (cont.)

- What is an external property?

An external property is similar to a case property or task property with the exception that an external property can be defined outside of IBM Case Manager and then bound to the Model API layer so that the data can be rendered in the Properties widget for example.

- External properties can be defined using
 - External Data Services
 - Java Servlets
 - JSON file on mid-tier
 - In-line in JavaScript

External Properties (cont.)

- General Use Case
 - *Most organizations maintain several “systems of record” data sources*
 - *These data sources often contain the most current “single source of truth”*
 - *Easy access to this information helps case workers complete their work*
 - *It is often necessary, and efficient, to access this data live and not store a copy*
- Specific Use Case
 - *While working a claim for a customer, an agent opens the case details*
 - *Along side the claim specific data, the agent sees the customer’s contact information, pulled live from their client database*
 - *A list of past transactions is also conveniently displayed, saving the agent from having to access another system*

External Properties (cont.)

- Placeholder added to a property view
- A script is added to the page that gets data from another system based on one of the existing case properties
- The returned data is mixed into the view with the case properties
- The external property is never persisted with the case data itself and is always accurate
- External properties can be both read-only and read-write

The screenshot displays the IBM Case Manager interface. On the left, a 'Contact Phone' field is highlighted with a blue border and contains the text 'No value'. A green callout box points to this field with the text 'External property placeholder added to view'. To the right, a 'Settings' panel is open, showing 'External Property Settings'. It includes fields for 'Collection ID' (set to 'External'), 'Property ID' (set to 'EXT_ContactPhone'), 'Type' (set to 'String'), and 'Multiple values' (unchecked). Below these, the 'Property Settings' section shows the 'Label' set to 'Contact Phone'. A green callout box points to the 'Contact Phone' label with the text 'External property value set at runtime'. At the bottom, the 'Overview' tab is selected, showing a form with fields for 'Contact Name' (Dave), 'Contact email' (dperman@ca.ibm.com), 'Contact Phone' (949-555-1212), 'Incident Date' (30/07/2014), and 'Incident Category'.
